a-) Fit a regression model with divorce as the response and unemployed, femlab, marriage, birth and military as predictors.

```

b-) For the same model, compute the VIFs. Is there evidence that collinearity causes some

predictors not to be significant? Explain.

There are significant non-linear effects between almost all of the factors.

There appears to be a non-linear pattern in the residuals. There appears to be non-uniform variance in the residuals.

Problem 2

Refer to the Machine speed Data, showing the number of defective items produced by a machine (Y) and the speed setting of the machine (X). Answer the questions below.

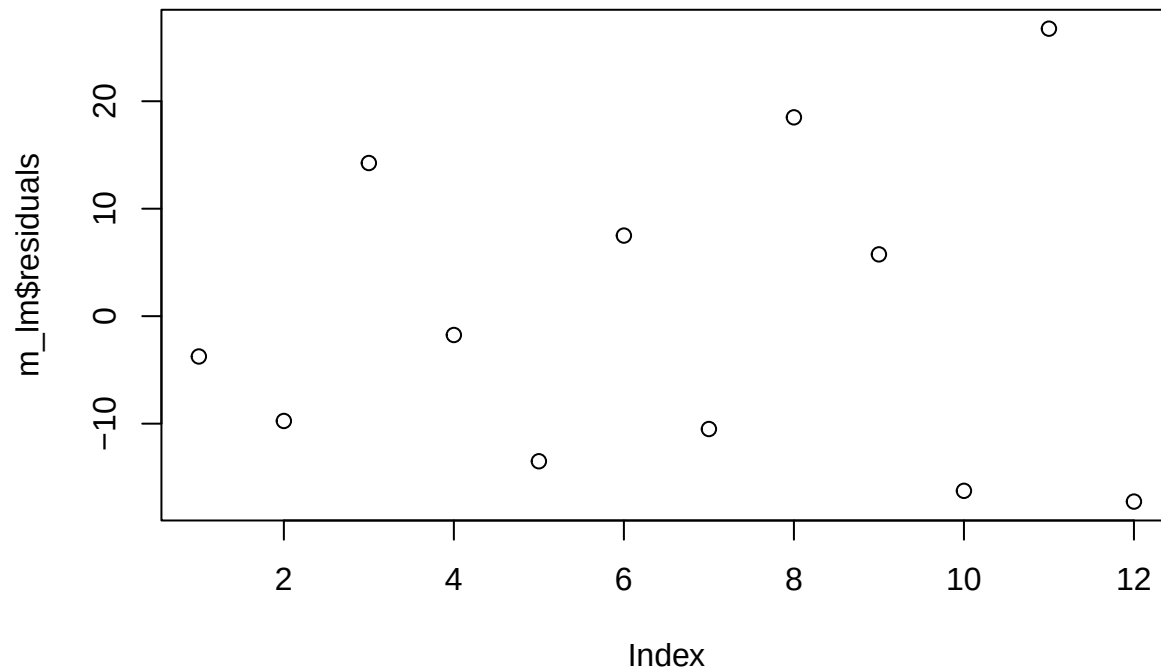

```
m_data = read.csv("Machine Speed.csv")
m_data = m_data[order(m_data$X), ]
tail(m_data)
```

```
##      Y    X
## 7  40 300
## 12 69 300
## 2   75 400
## 4   53 400
## 8   96 400
## 10  52 400
```

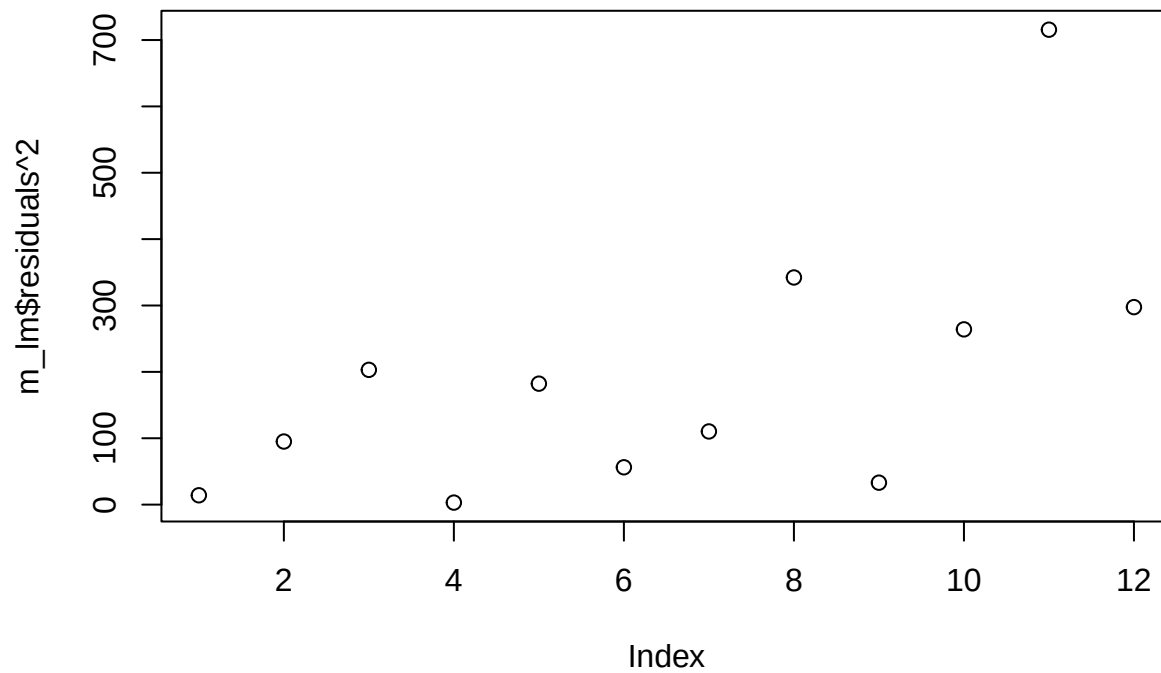

a-) Fit a linear regression function by ordinary least squares, obtain the residuals, and plot the residuals against X. Plot the squared residuals against X.

```
m_lm = lm(Y ~ X, m_data)
summary(m_lm)
```

```
##
## Call:
## lm(formula = Y ~ X, data = m_data)

plot(m_lm$residuals)
```

```
plot(m_lm$residuals^2)
```

What do the plots suggest?

The variance appears to increase with X .

b-) Conduct the Breusch-Pagan test for constancy of the error variance, use $\alpha = .10$. State the alternatives, decision rule, and conclusion.

Null Hypothesis: The error variance is homoscedastic.

Alternative Hypothesis: The error variance is heteroscedastic.

```
bptest(m_lm)
```

```
##
## studentized Breusch-Pagan test
##
## data: m_lm
## BP = 3.3723, df = 1, p-value = 0.0663
```

At $\alpha = 0.10$, we have $0.07 < 0.10$, so we cannot discharge the null hypothesis.

c-) Calculate the weights for weighted least square estimation and refit the model.

```
residuals_x = data.frame(residuals = abs(m_lm$residuals), X= m_data$X)
var_est = predict(lm(residuals ~ X, residuals_x), new_data = m_data$X)
weights = 1 / var_est

```

d-) Are the weighted least squares estimates of β_0 and β_1 similar to the ones obtained with ordinary least squares in part (a)?

```
print(m_lm$coefficients)
```

```
## (Intercept)          X
##      -5.7500       0.1875
```

```
print(m_lm_weighted$coefficients)
```

```
## (Intercept)          X
## -6.0322165    0.1884407
```

The weights are similar in order and direction. They differ slightly.

e-) Compare the estimated standard deviations of the weighted least squares estimates $b\beta_{w0}$ and β_{w1} in part (c) with those for the ordinary least squares estimates in part (a). What do you find?

```
print(summary(m_lm)$coefficients[, "Std. Error"])

```

```
## (Intercept)          X  
## 14.41414871 0.05058382
```

The standard errors for the weighted model are slightly lower.

f-) Iterate the steps in parts (c) one more time. Is there a substantial change in the estimated regression coefficients? If so, what should you do?

```
residuals_x = data.frame(residuals = abs(m_lm_weighted$residuals), X= m_data$X)  
var_est = predict(lm(residuals ~ X, residuals_x), new_data = m_data$X)  
weights = 1 / var_est

```

The estimates, Multiple R-squared, and Std. Error do not change significantly.

If there was a marginal improvement over the last iteration, you would probably want to continue iterating until the improvement becomes insignificant.

Problem 3

Refer to the CDI data set used in Assignment 5. For this analysis, use all variables except Identification Number, County, and State. In addition, include the dummy variables you created for Geographic Region in Question 1(a) of Assignment 5, and remove the original Geographic Region variable. The dependent variable is the number of active physicians (Y), which should be regressed on all remaining variables, including the geographic-region dummy variables.

```
cdi_data_raw = read.csv("CDI Data.csv")  
ignore = c("Identification.number", "County", "State")  
cdi_data = subset(cdi_data_raw, select = -match(ignore, names(cdi_data_raw)))  
cdi_data$Geographic.region = factor(cdi_data$Geographic.region)  
tail(cdi_data)

The error variance is clearly heteroscedastic.

b-) The CDI data set contains 440 observations. Randomly divide the data into five folds, each containing 88 observations, using `set.seed(1023)` to ensure reproducibility. Perform 5-fold cross-validation to assess the stability of your selected model in part a. For each fold, report the following metrics for both the training and testing sets:

- Root Mean Squared Error (RMSE)
- R-squared (R^2)
- Mean Absolute Error (MAE)

```
cdi_train_kfold <- trainControl(method = "cv", number = 5, savePredictions = "all")

The range of Rsquared is ~17%. The least Rsquared is ~0.81. This model explains most of the variability in the number of active physicians.
